

Installing Medulla on Linux

Prerequisites:

The Medulla installation script supports the Debian (Bookworm) distribution.

You must have a machine with:

- **at least 8 GB of available RAM,**
- **at least 40 GB of free disk space for / and 200 GB for /var.**

Verify that your **/etc/hosts** file is properly configured with the full FQDN.

For example, if the machine is named medulla and the domain is named domain.lan, the **/etc/hosts** file must contain a line like this:

```
127.0.1.1    medulla.domain.lan    medulla
```

Verify that the **/etc/resolv.conf** file **is** properly configured and that the machine is connected to the internet.

Installing the Medulla server:

To install the Medulla server: Use a user with sudo privileges to run the installation script and playbook.

1- Transfer the script to the server.

2- Set execute permissions on the file:

```
type: chmod +x install_from_ansible.py
```

3- Start the server installation:

```
./install_from_ansible.py
```

Wait for the installation process to finish; a summary will display all the necessary passwords (copy them to a safe place).
